Assembly Language GCD Code

A family tree of languages

Some of the 2400 + programming languages

Why are there so many programming languages?

1. Evolution
2. Socio-Economic Reasons
3. Orientation toward special purposes
4. Orientation toward special hardware

Scala

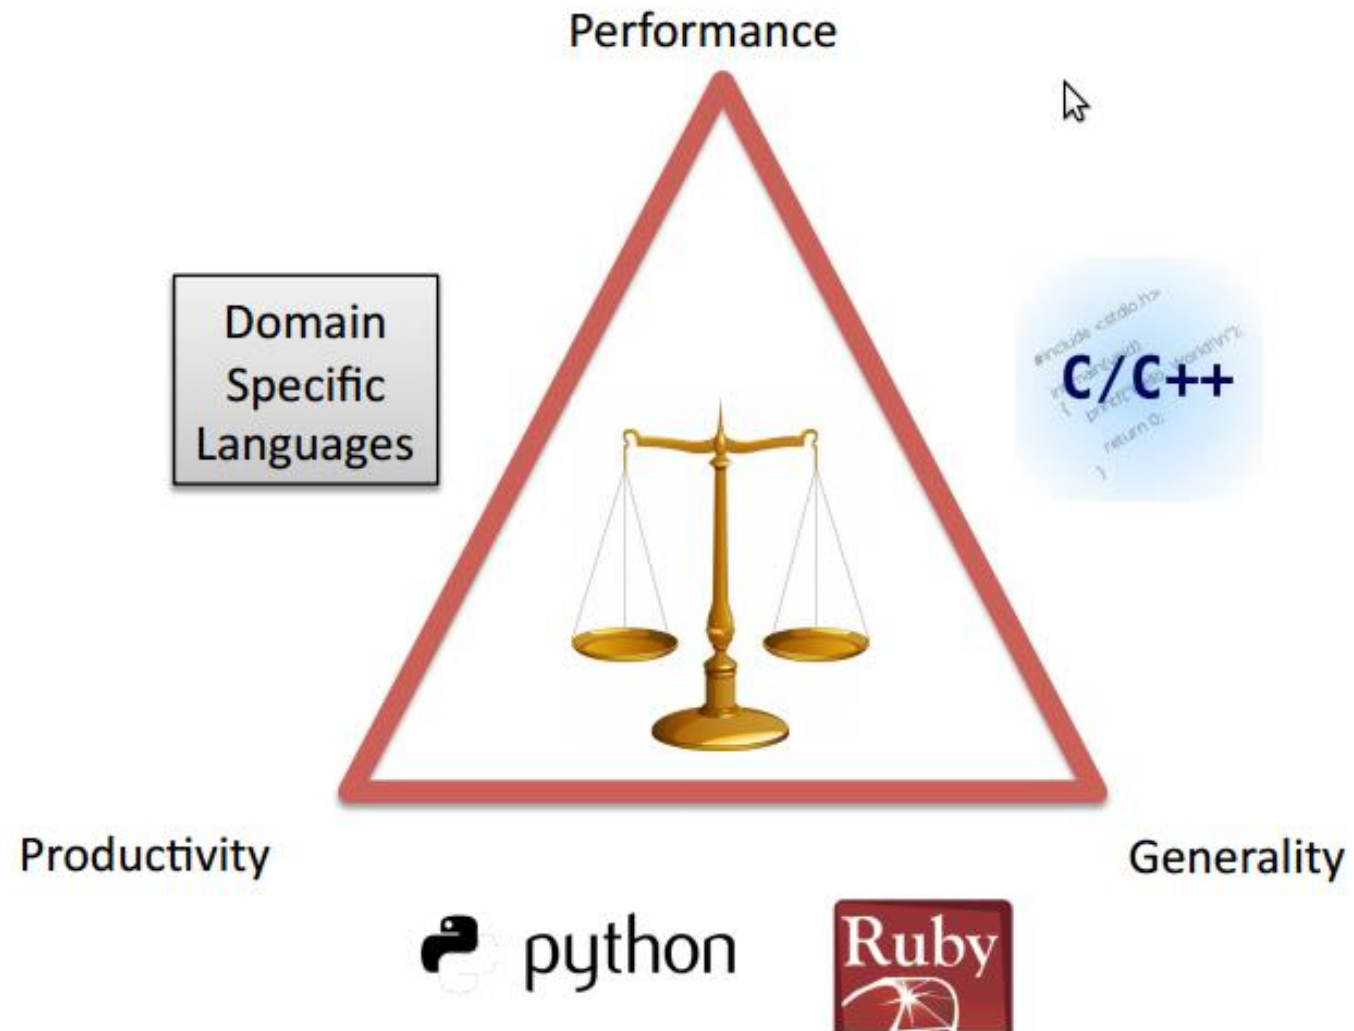

Kotlin

Dart

Swift

What makes a language successful?

1. easy to learn (BASIC, Pascal, LOGO, Scheme)
2. easy to express things, easy use once fluent, "powerful" (C, Common Lisp, APL, Algol-68, Perl)
3. easy to implement (BASIC, Forth, Python)
4. possible to compile to very good (fast/small) code (Fortran, C)
5. backing of a powerful sponsor (COBOL, PL/1, Ada, Visual Basic, C#)
6. wide dissemination at minimal cost (Pascal, Turing, Java, JavaScript)

Why do we have programming languages? What is a language for?

1. way of thinking -- way of expressing algorithms
2. languages from the user's point of view
3. abstraction of virtual machine -- way of specifying what you want
4. the hardware to do without getting down into the bits
5. languages from the implementator's point of view

```
int gcd(int a, int b) {  
    while (a != b) {  
        if (a > b) a = a - b;  
        else b = b - a;  
    }  
    return a;  
}
```

// C

```
let rec gcd a b =  
    if a = b then a  
    else if a > b then gcd b (a - b)  
    else gcd a (b - a)
```

(* OCaml *)

```
gcd(A,B,G) :- A = B, G = A.  
gcd(A,B,G) :- A > B, C is A-B, gcd(C,B,G).  
gcd(A,B,G) :- B > A, C is B-A, gcd(C,A,G).
```

% Prolog

The Interpretation of Computer Programs

SECTION 3 INTERPRETATION VERSUS COMPILATION

Purpose of Compilation and Interpretation

Convert a language to another language or machine language for execution.

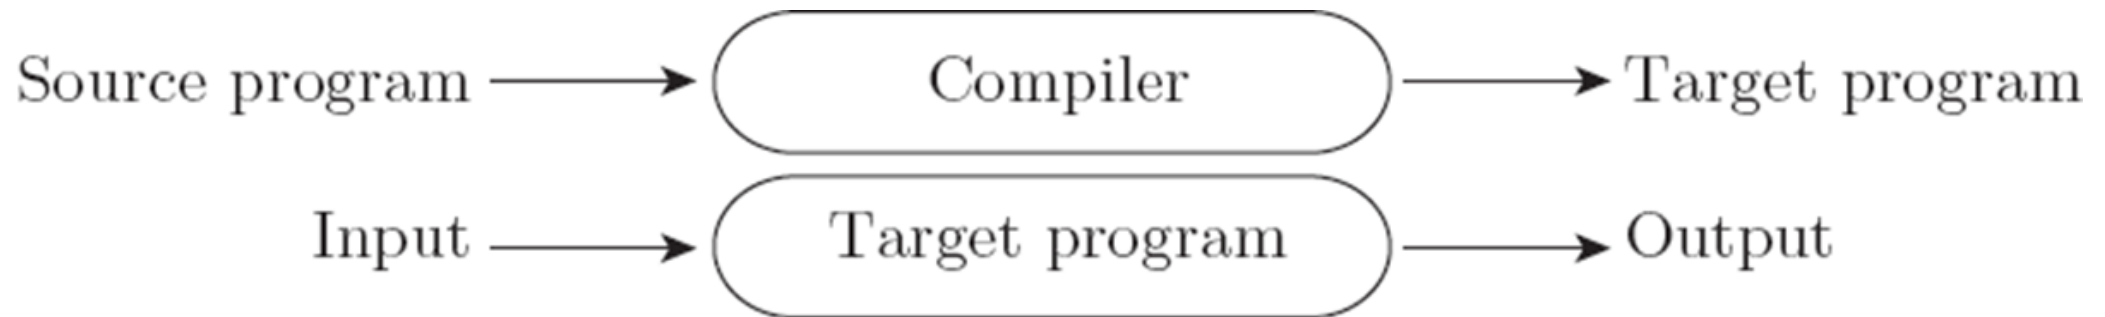

Pure Compilation

C -> Machine Code; C -> Java?

The compiler translates the high-level source program into an equivalent target program (typically in machine language), and then goes away:

Is it OK to compile C into Java?

Pure Interpretation

1. Interpreter stays around for the execution of the program
2. Interpreter is the locus of control during execution

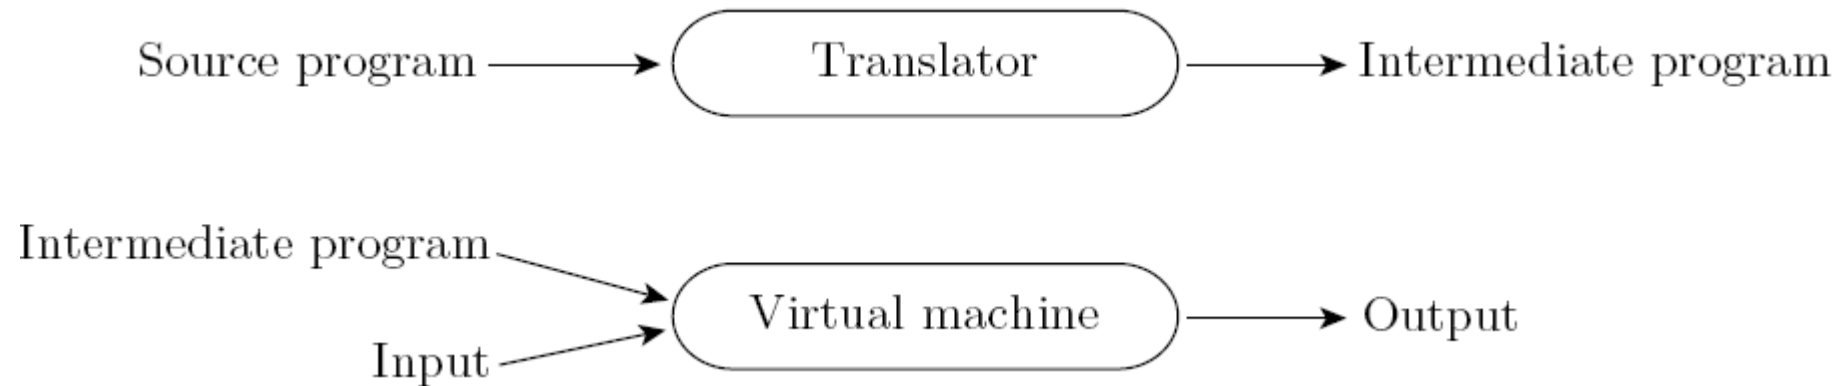

Comparison

- Interpretation:
 - Greater flexibility
 - Better diagnostics (error messages)
- Compilation
 - Better performance

Hybrids

- Common case is compilation or simple pre-processing, followed by interpretation
- Most modern language implementations include a mixture of both compilation and interpretation

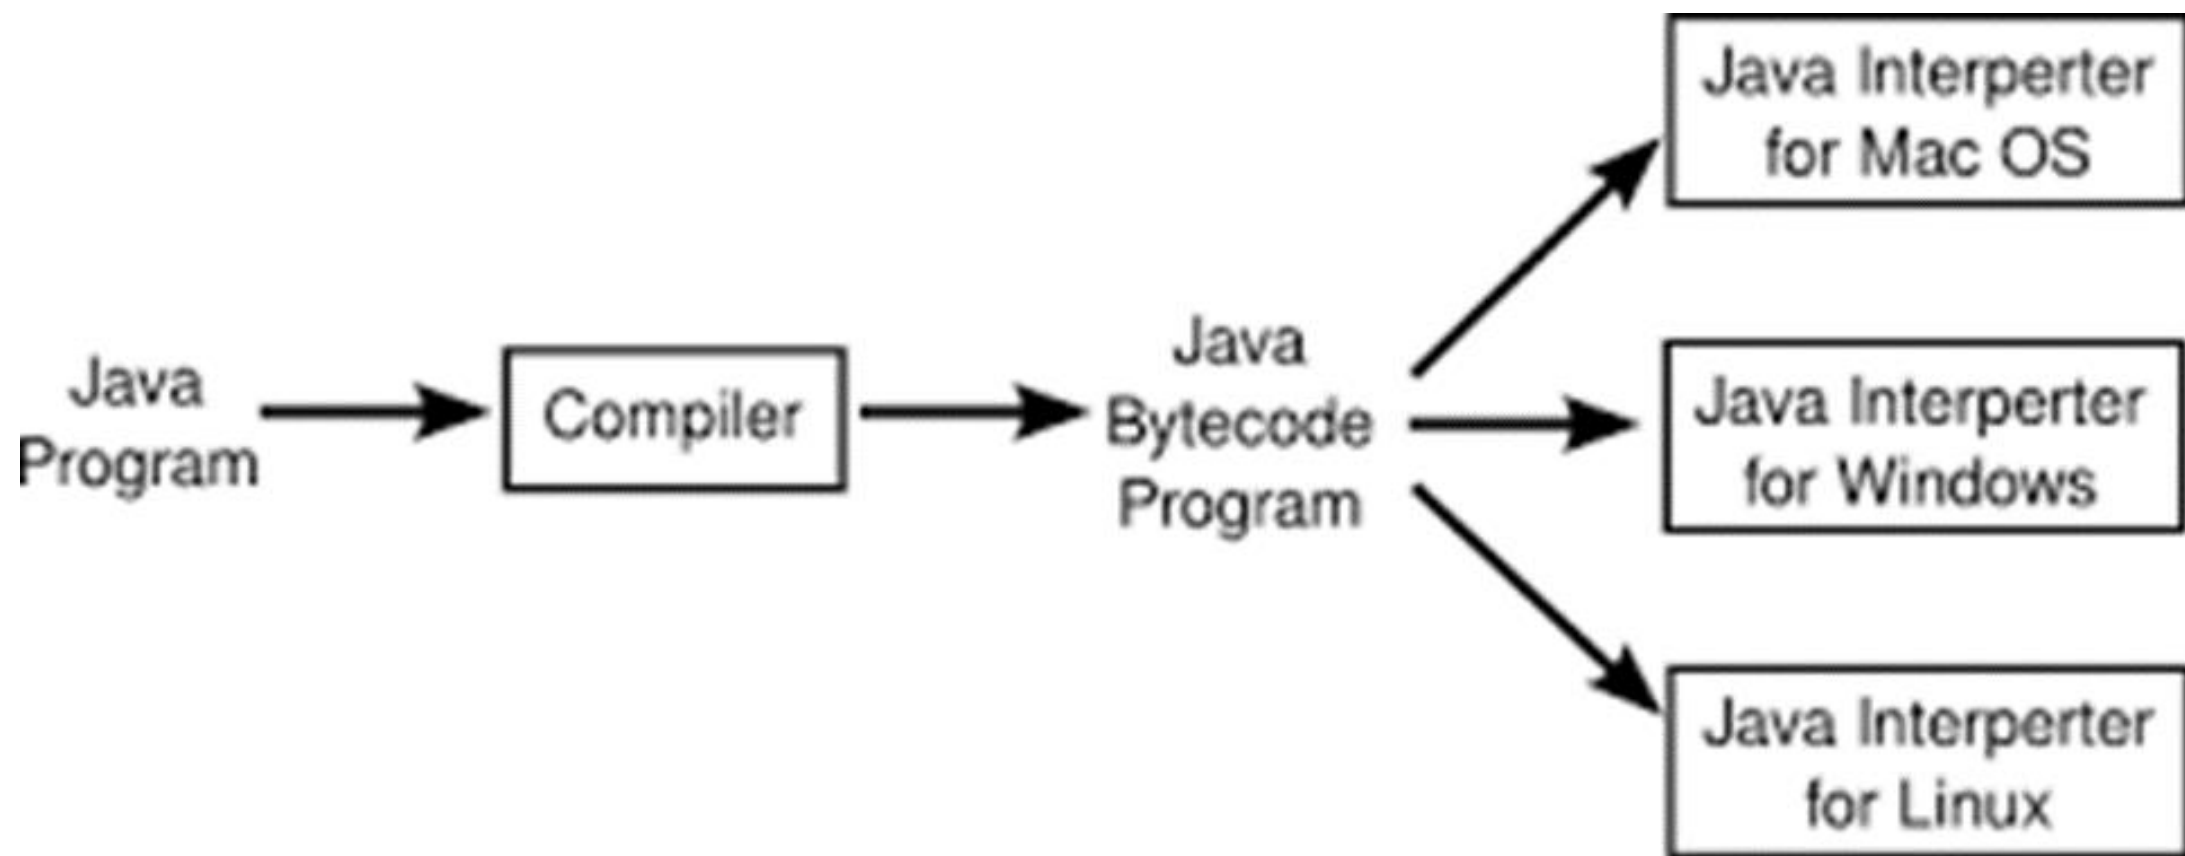

Virtual Machines

Step 1: Compilation from Java to Byte Code

Step 2: Executing the byte code on a machine with native codes

The Interpretation of Computer Programs

SECTION 4 COMPILATION STRATEGY

Compilation Strategies

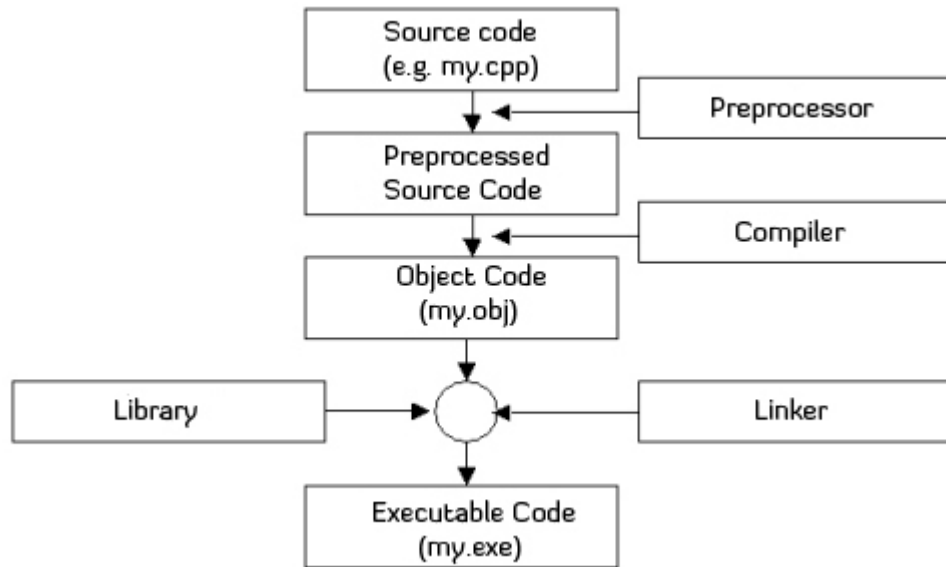

- Every language may use one or more compilation strategies.
- Examples are shown for certain language, but it may not be the only language to use that strategy.

(A) Preprocessor

Tokens

- Removes comments and white space
- Groups characters into tokens (keywords, identifiers, numbers, symbols)
- Expands abbreviations in the style of a macro assembler
- Identifies higher-level syntactic structures (loops, subroutines)

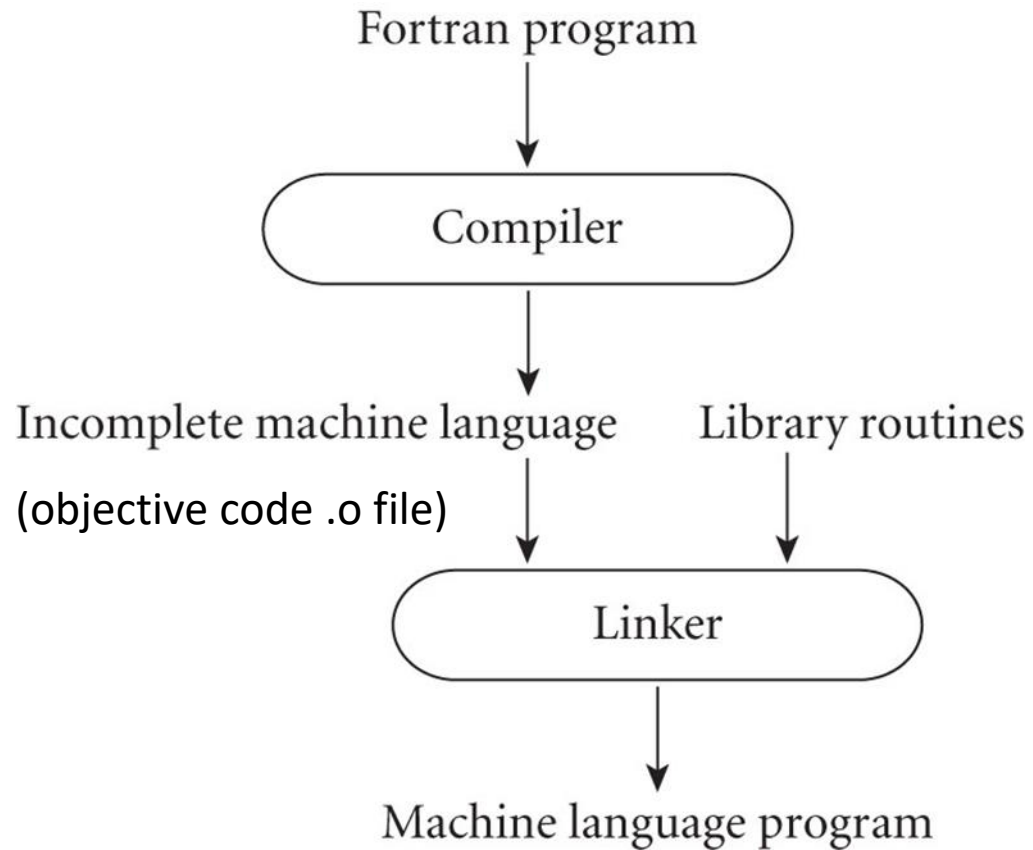

C/C++ Preprocessor

Different preprocessor directives (commands) perform different tasks. We can categorize the Preprocessor Directives as follows:

- Inclusion Directives (**#include**)
- Macro Definition Directives (**#define #undef**)
- Conditional Compilation Directives (**#if, #elif, #endif, #ifdef, #ifndef**)
- Other Directives (**#error, #line, #pragma**)

(B) Library of Routines and Linking

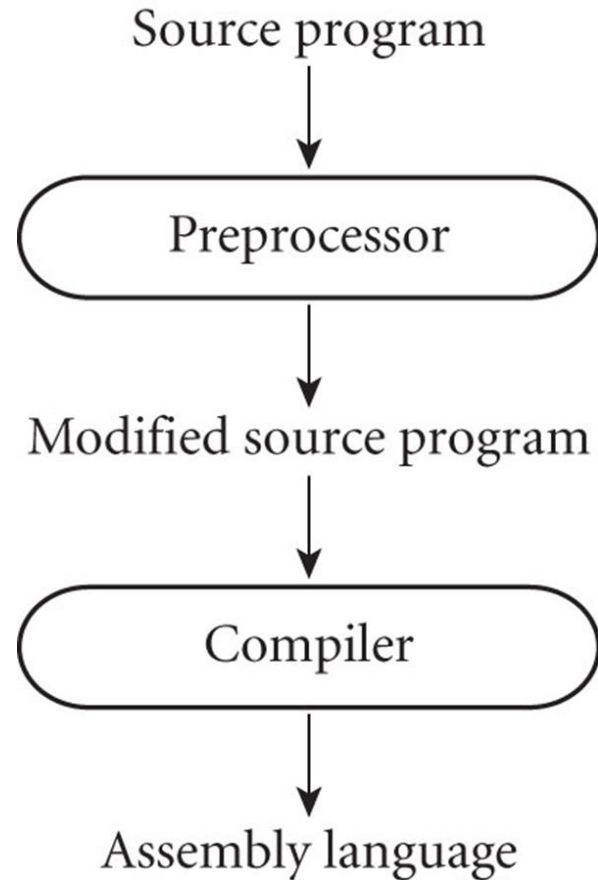

- Compiler uses a linker program to merge the appropriate library of subroutines (e.g., math functions such as sin, cos, log, etc.) into the final program:

(C)Post-compilation Assembly

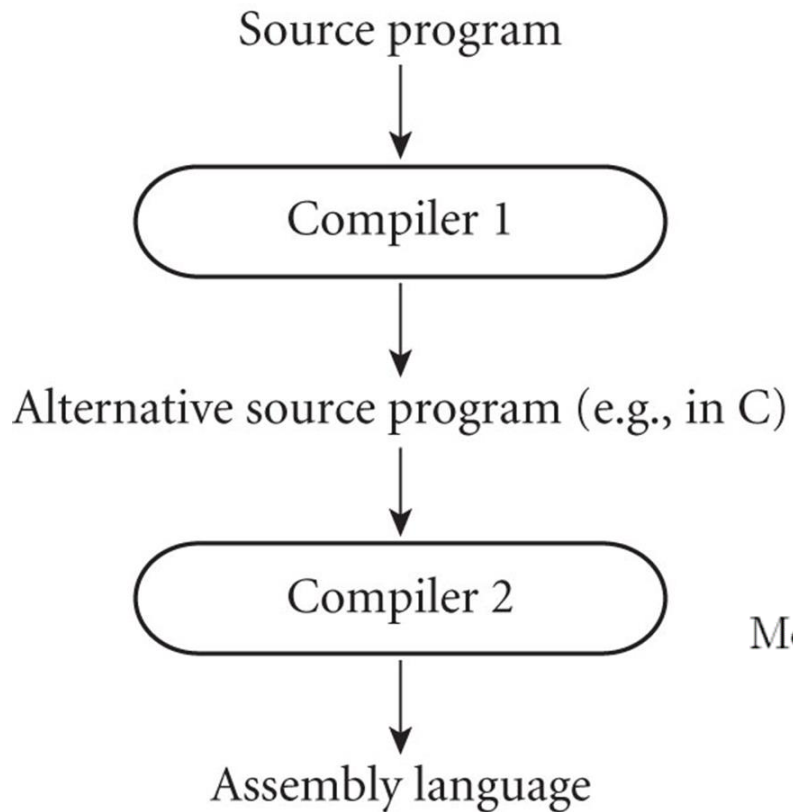

- Facilitates debugging (assembly language easier for people to read)
- Isolates the compiler from changes in the format of machine language files (only assembler must be changed, is shared by many compilers)

(D) The C Preprocessor (conditional compilation)

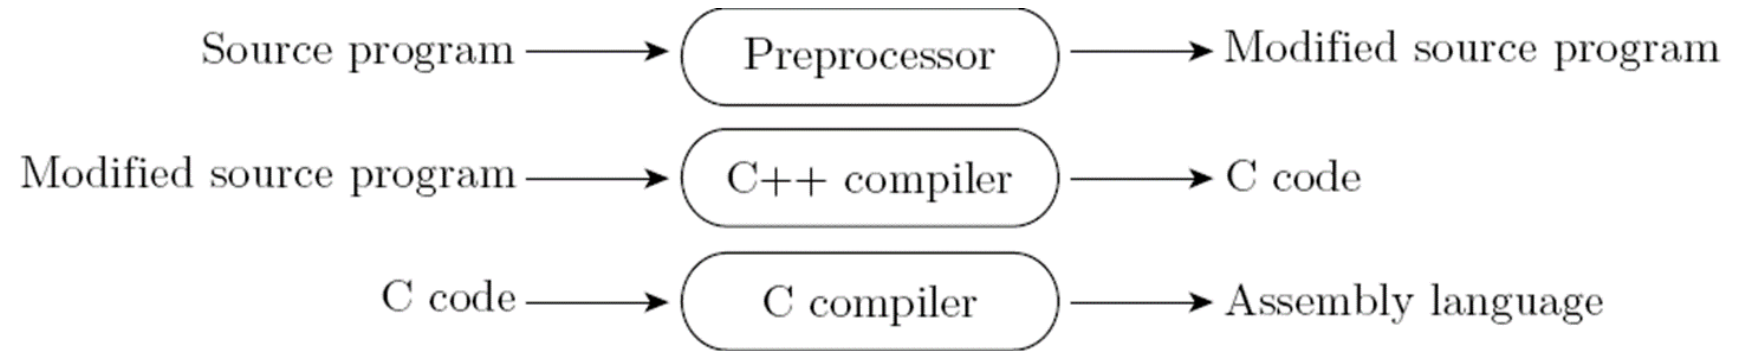

- Preprocessor deletes portions of code, which allows several versions of a program to be built from the same source

(E) Source-to-Source Translation (C++)

- C++ implementations based on the early AT&T compiler generated an intermediate program in C, instead of an assembly language: (combination of A and E)

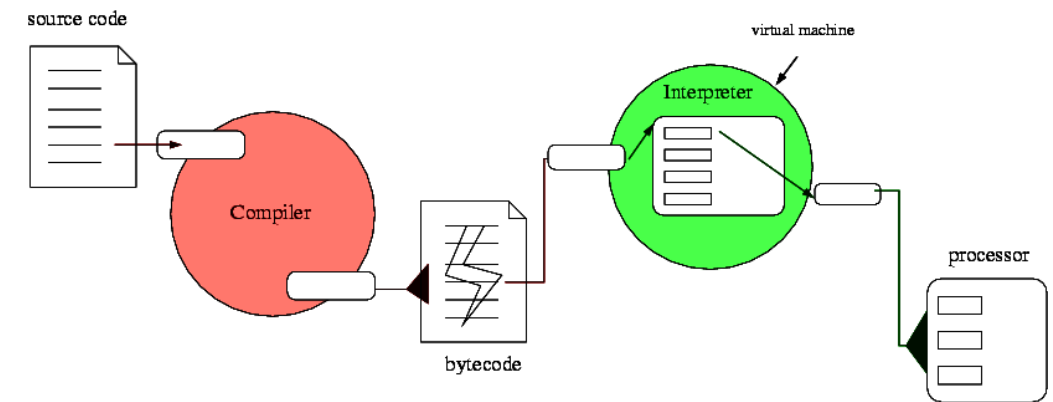

The Interpretation of Computer Programs

SECTION 5 INTRODUCTION STRATEGY

(F) Compilation of Interpreted Languages

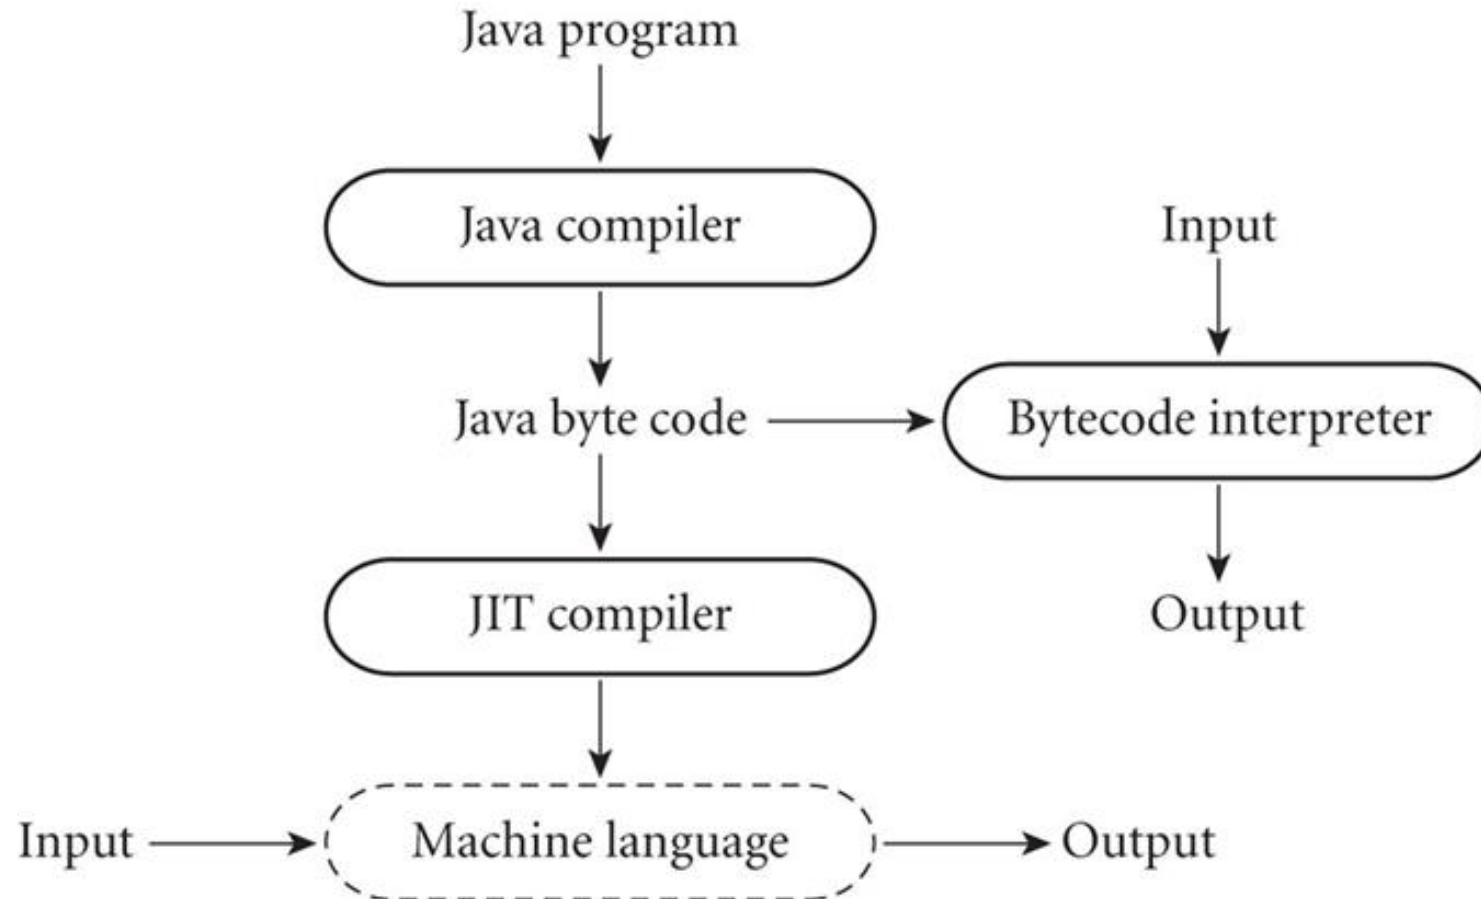

- The compiler generates code that makes assumptions about decisions that won't be finalized until runtime. If these assumptions are valid, the code runs very fast. If not, a dynamic check will revert to the interpreter.

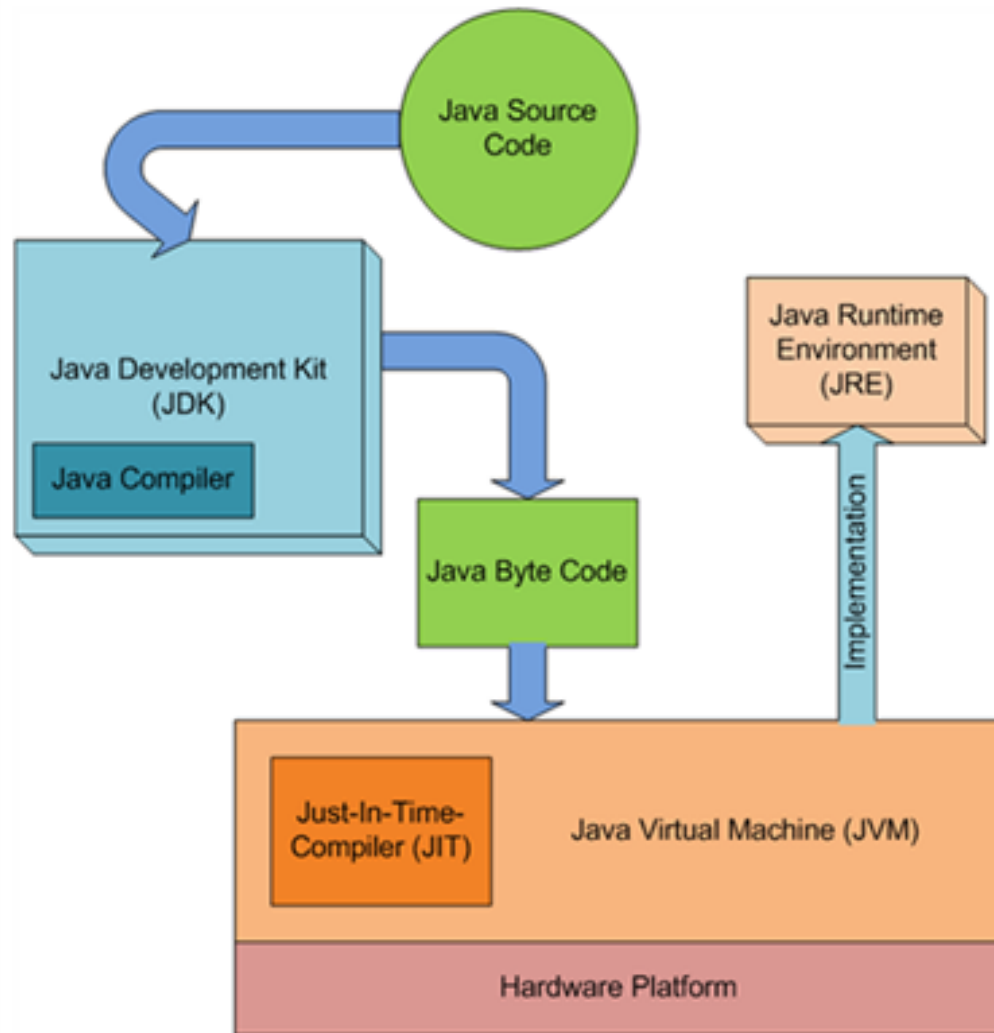

(G) Dynamic and Just-in-Time Compilation

- In some cases a programming system may deliberately delay compilation until the last possible moment.
- Lisp or Prolog invoke the compiler on the fly, to translate newly created source into machine language, or to optimize the code for a particular input set.
- The Java language definition defines a machine-independent intermediate form known as byte code. Byte code is the standard format for distribution of Java programs.
- The main C# compiler produces .NET Common Intermediate Language (CIL), which is then translated into machine code immediately prior to execution.

Java JIT

Just-In Time
Compilation
Wait until
you can no
longer wait!

JDK

`javac, jar, debugging tools,
javap`

JRE

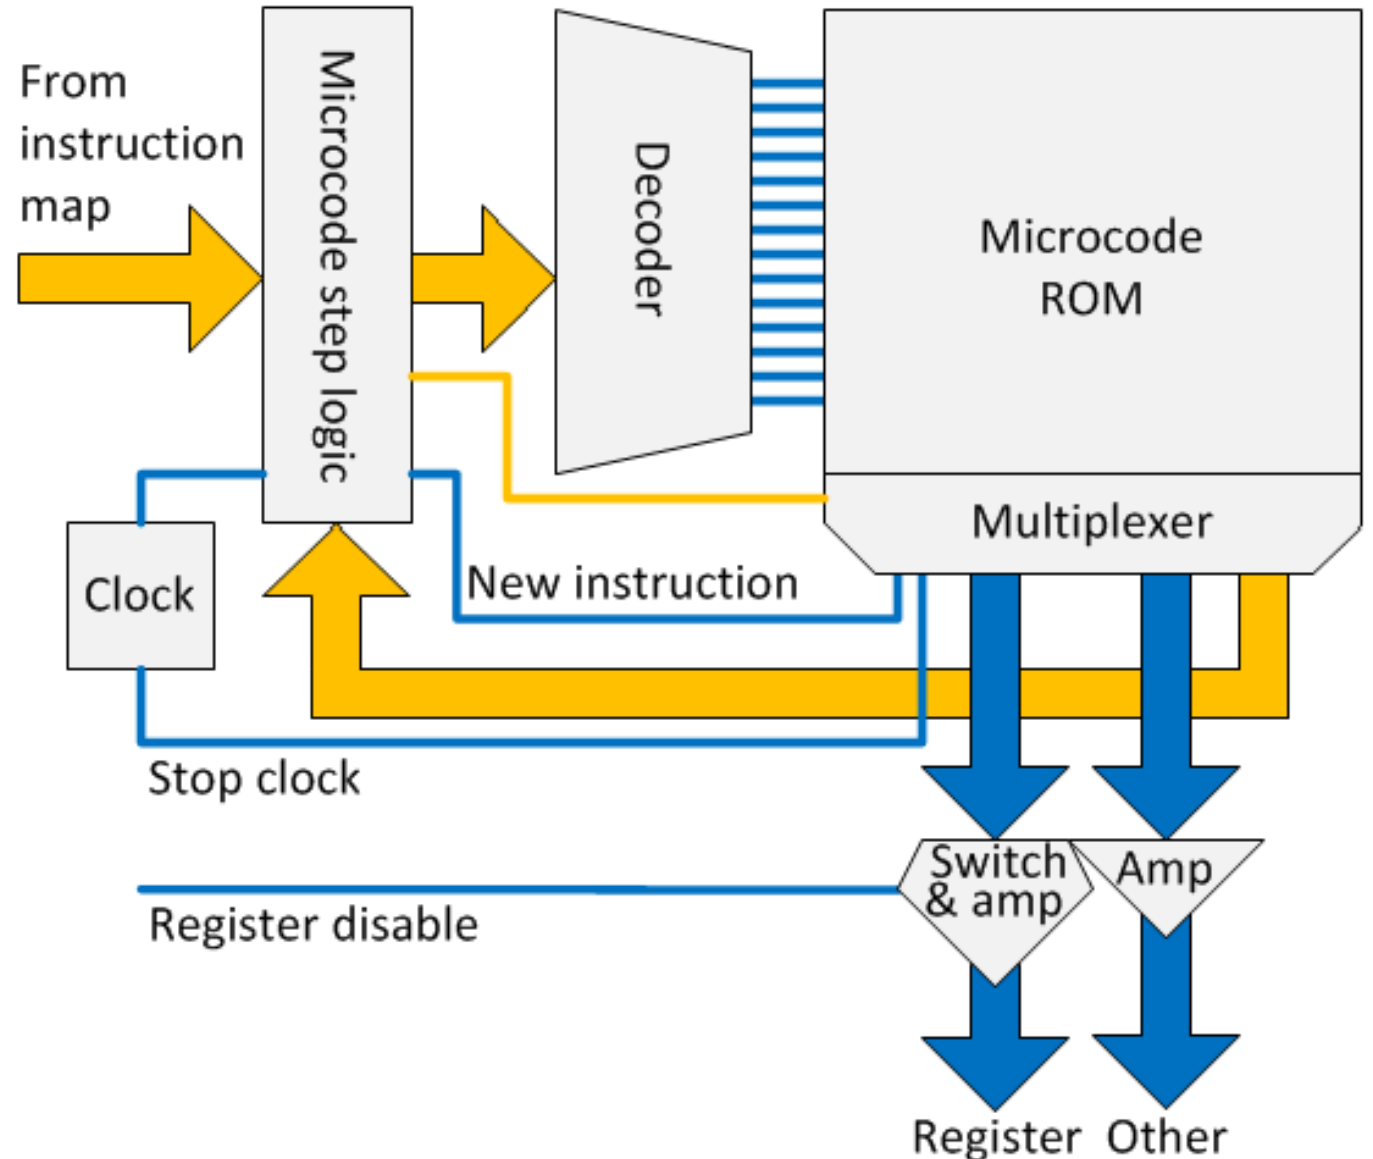

`java, javaw, libraries,
rt.jar`

JVM

Just In Time
Compiler (JIT)

(H) Microcode Instruction is Translated to Microcode

- Assembly-level instruction set is not implemented in hardware; it runs on an interpreter.
- Interpreter is written in low-level instructions (microcode or firmware), which are stored in read-only memory and executed by the hardware.

Program Environment

SECTION 6

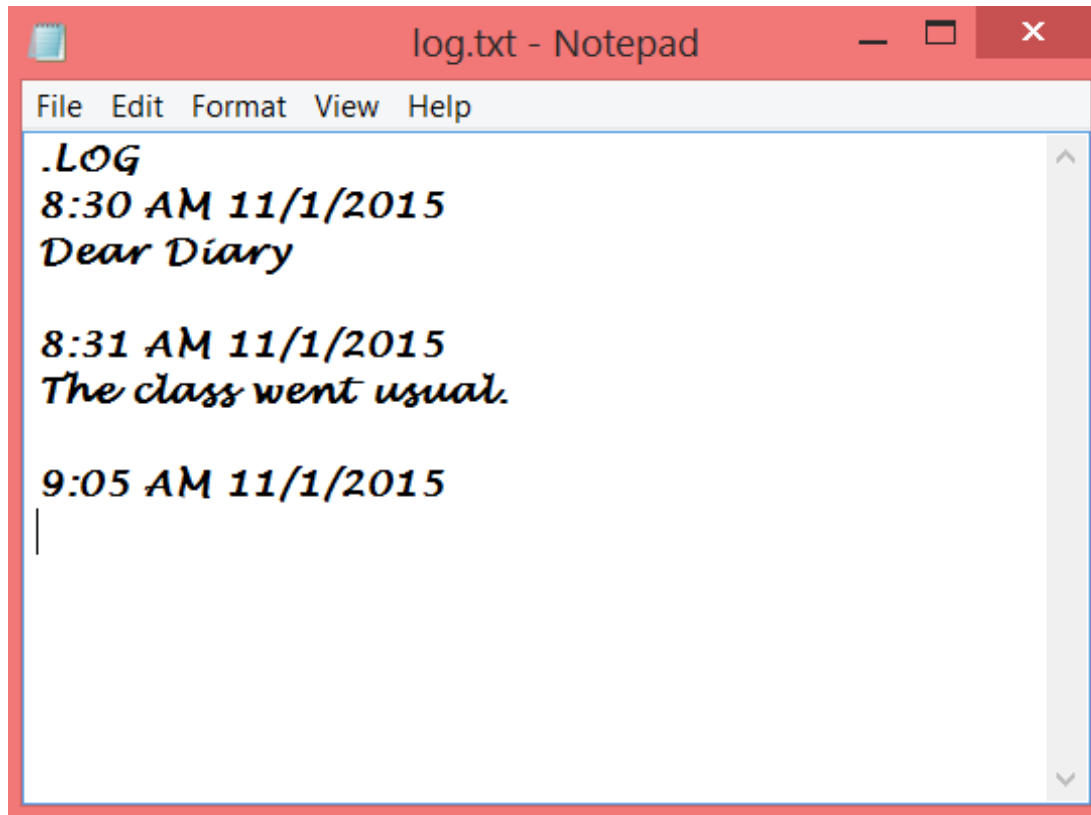

Unix Tools

Still Widely Used in Linux-based Systems

Type	Unix examples
Editors	vi, emacs
Pretty printers	cb, indent
Pre-processors (esp. macros)	cpp, m4, watfor
Debuggers	adb, sdb, dbx, gdb
Style checkers	lint, purify
Module management	make
Version management	sccs, rcs
Assemblers	as
Link editors, loaders	ld, ld-so
Perusal tools	More, less, od, nm
Program cross-reference	ctags

Source Code Editor

Notepad, Notepad++

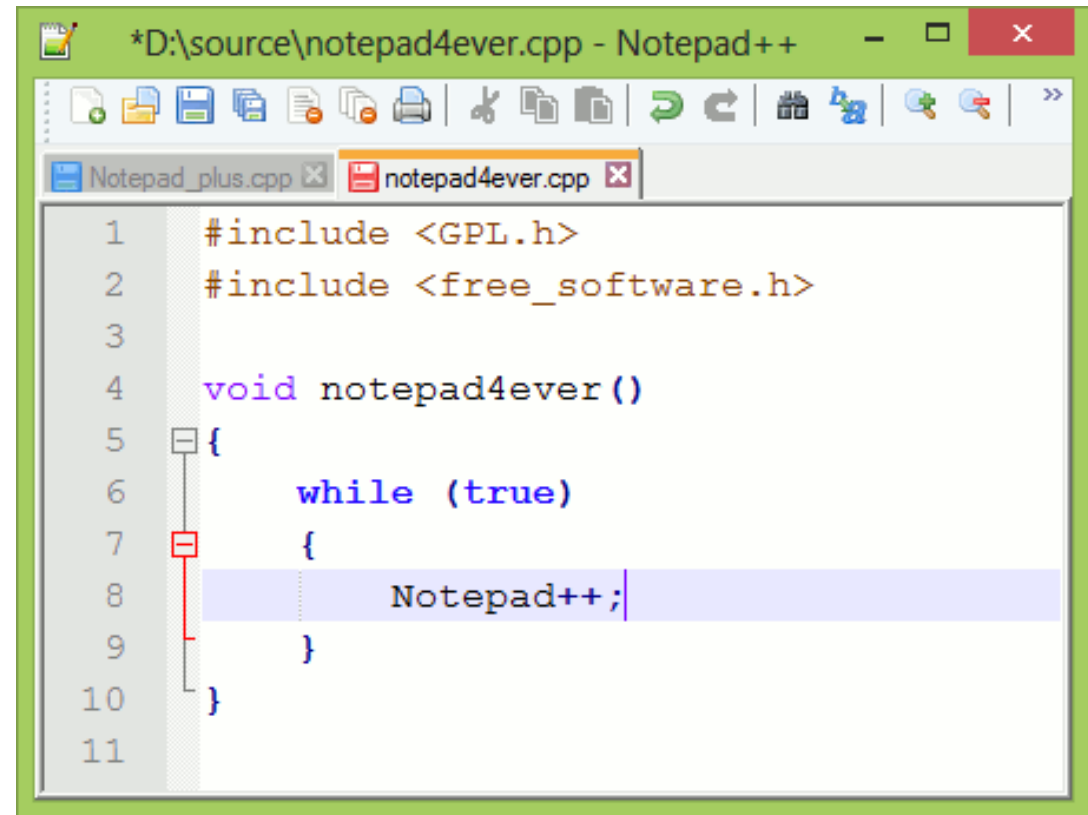

A screenshot of the Notepad application window titled "log.txt - Notepad". The window has a menu bar with "File", "Edit", "Format", "View", and "Help". The text content is as follows:

```
.LOG
8:30 AM 11/1/2015
Dear Diary

8:31 AM 11/1/2015
The class went usual.

9:05 AM 11/1/2015
|
```

A screenshot of the Notepad++ application window titled "*D:\source\notepad4ever.cpp - Notepad++". The window has a menu bar and a toolbar. The code content is as follows:

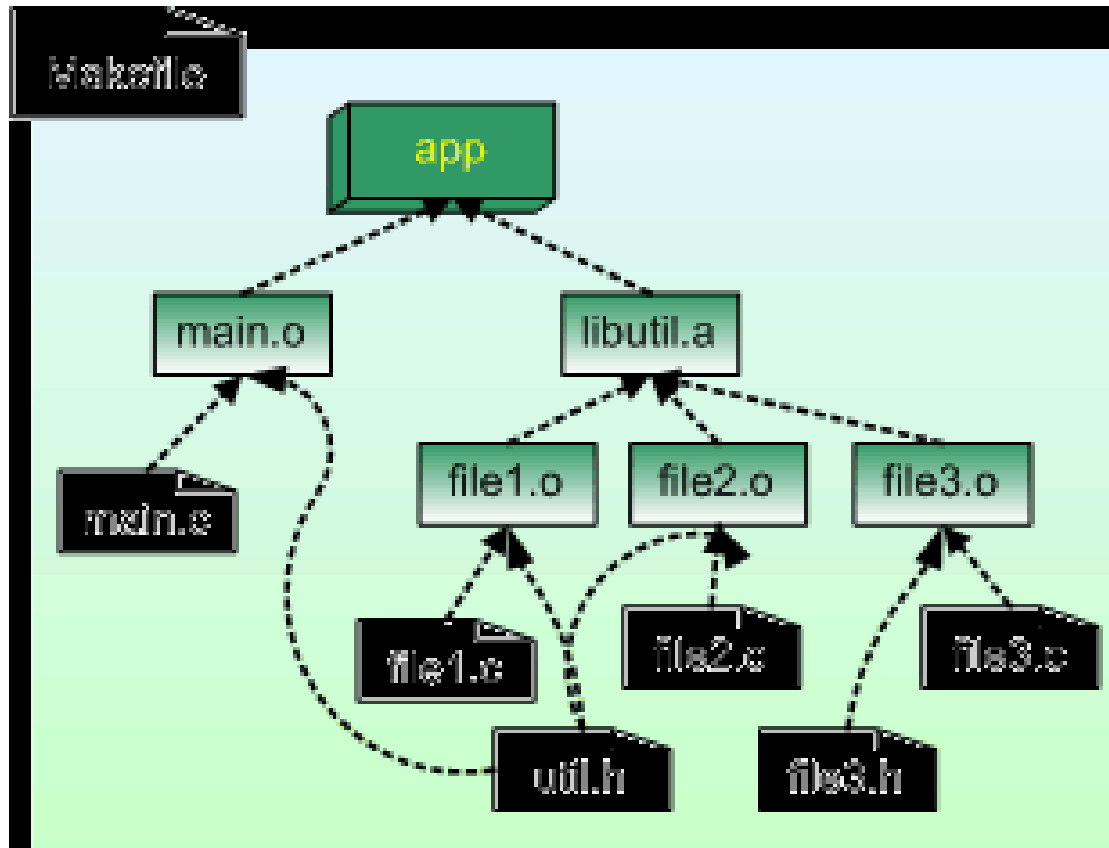

```
1  #include <GPL.h>
2  #include <free_software.h>
3
4  void notepad4ever()
5  {
6      while (true)
7      {
8          Notepad++;
9      }
10 }
11
```

Compilation: The Analysis of Computer Program Structures

SECTION 7 SIX PHASES

Phases of Compilation

Scanning

Lexical Analysis

- divides the program into "**tokens**", which are the smallest meaningful units; this saves time, since character-by-character processing is slow
- we can tune the scanner better if its job is simple; it also saves complexity (lots of it) for later stages
- you can design a parser to take characters instead of tokens as input, but it isn't pretty
- scanning is recognition of a regular language, e.g., via **DFA**

DFA: Deterministic Finite Automaton

Deterministic Finite Automaton

Non-Random Finite State Machine

In Computer Science, a deterministic finite automaton (**DFA**)—also known as a deterministic finite accepter (**DFA**) and a deterministic finite state machine (**DFSM**)—is a finite-state machine that accepts and rejects finite strings of symbols and only produces a unique computation (or run) of the automaton for each input string.

The following example is of a DFA M , with a binary alphabet, which requires that the input contains an even number of 0s.

$M = (Q, \Sigma, \delta, q_0, F)$ where

- $Q = \{S_1, S_2\}$,
- $\Sigma = \{0, 1\}$,
- $q_0 = S_1$,
- $F = \{S_1\}$, and
- δ is defined by the following state transition table:

	0	1
S_1	S_2	S_1
S_2	S_1	S_2

Parsing is recognition of a context-free language, e.g., via PDA

- Parsing discovers the "context free" structure of the program
- Informally, it finds the structure you can describe with syntax diagrams (the "circles and arrows" in a Pascal manual)

Syntax Analysis

PDA: Push Down Automaton

Push Down Automaton

In computer science, a pushdown automaton (PDA) is a type of automaton that employs a stack.

States are stored in stack.

Semantic analysis is the discovery of meaning in the program

The compiler actually does what is called **STATIC** semantic analysis. That's the meaning that can be figured out at compile time

Some things (e.g., array subscript out of bounds) can't be figured out until run time. Things like that are part of the program's **DYNAMIC** semantics (Exception and Error)

Semantic Analysis

Intermediate form (IF) done after semantic analysis (if the program passes all checks)

- IFs are often chosen for machine independence, ease of optimization, or compactness (these are somewhat contradictory)
- They often resemble machine code for some imaginary idealized machine; e.g. a stack machine, or a machine with arbitrarily many registers
- Many compilers actually move the code through more than one IF

Semantic Analysis

Last Two Phases

- **Optimization** takes an intermediate-code program and produces another one that does the same thing faster, or in less space
 - The term is a misnomer; we just improve code
 - The optimization phase is optional
- **Code generation phase** produces assembly language or (sometime) relocatable machine language

Code Optimization

Code Generation

Machine-specific Optimization and Symbol Table

- Certain **machine-specific optimizations** (use of special instructions or addressing modes, etc.) may be performed during or after **target code generation**
- **Symbol table:** all phases rely on a symbol table that keeps track of all the identifiers in the program and what the compiler knows about them
- This symbol table may be retained (in some form) for use by a debugger, even after compilation has completed

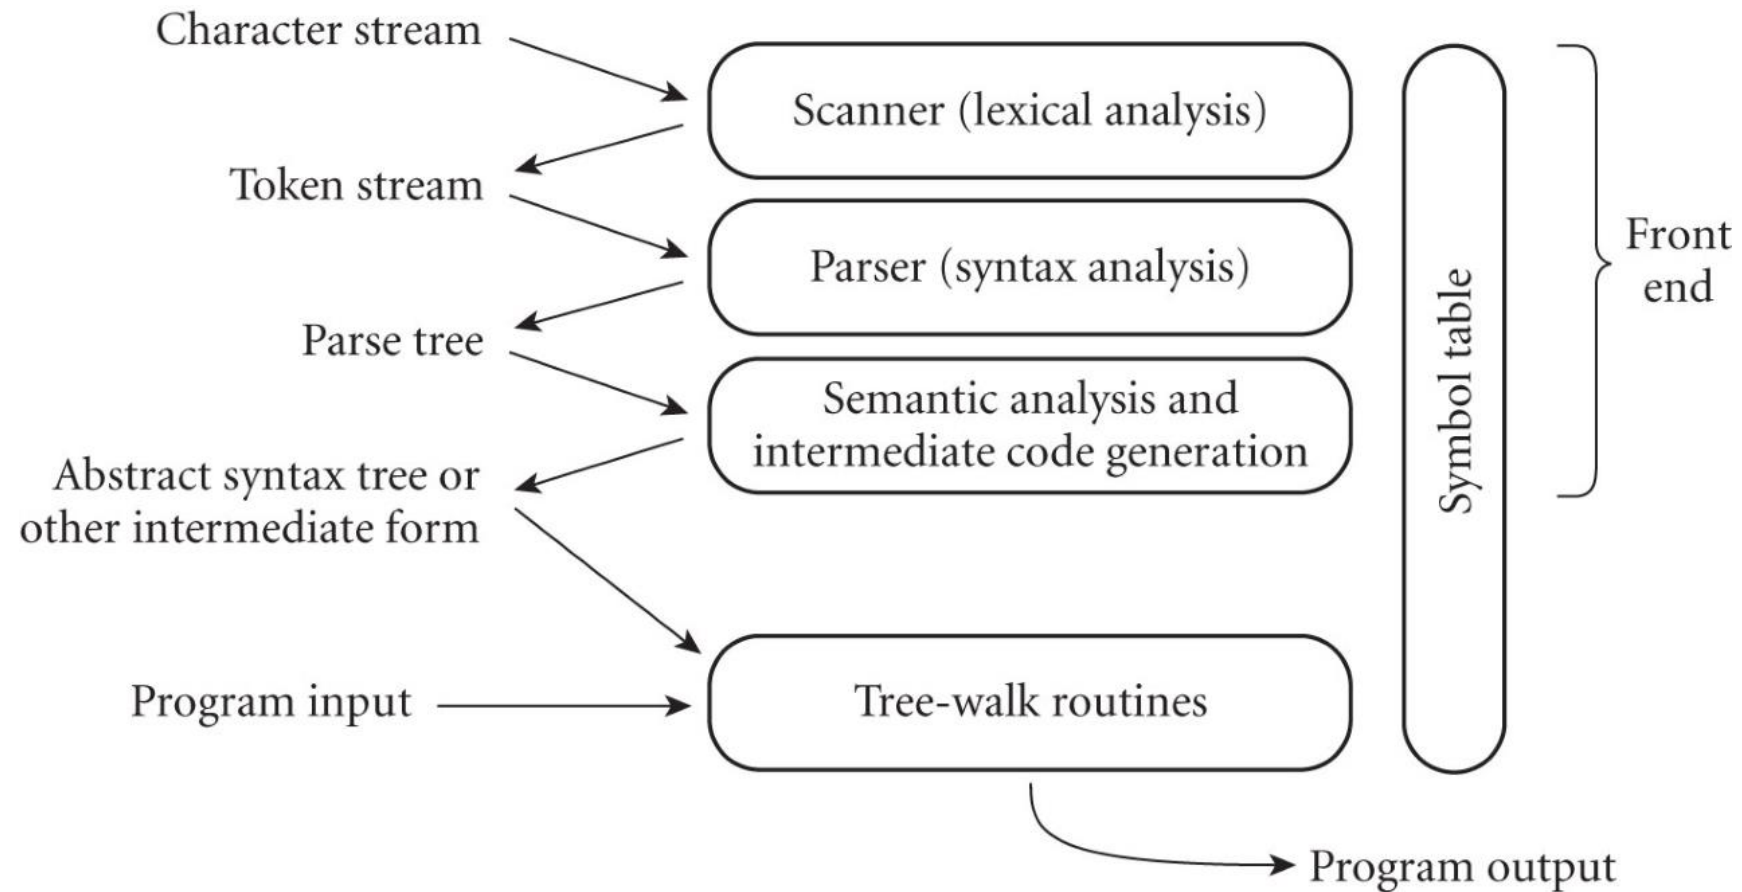

Code Generation

Symbol Table

Compilation: The Analysis of Computer Program Structures

SECTION 8 FRONT-END COMPILER

Front-End Compiler

Lexical and Syntax Analysis

GCD Program (in C)

```
int main() {  
    int i = getint(), j = getint();  
    while (i != j) {  
        if (i > j) i = i - j;  
        else j = j - i;  
    }  
    putint(i);  
}
```

Lexical and Syntax Analysis

- GCD Program Tokens
 - Scanning (lexical analysis) and parsing recognize the structure of the program, groups characters into tokens, the smallest meaningful units of the program

```
int      main    (    )      {  
int      i      =    getint  (    )    ,    j      =    getint  (    )    ;  
while    (      i    !=    j    )    {  
if      (      i    >    j    )    i    =    i    -    j    ;  
else     j      =    j      -    i    ;  
}  
putint   (      i    )      ;  
}
```

Lexical and Syntax Analysis

- Context-Free Grammar and Parsing
 - Parsing organizes tokens into a parse tree that represents higher-level constructs in terms of their constituents
 - Potentially recursive rules known as context-free grammar define the ways in which these constituents combine

Context-Free Grammar and Parsing

Example (while loop in C)

$\text{iteration-statement} \rightarrow \text{while (expression) statement}$

statement, in turn, is often a list enclosed in braces:

$\text{statement} \rightarrow \text{compound-statement}$

$\text{compound-statement} \rightarrow \{ \text{block-item-list opt} \}$

where

$\text{block-item-list opt} \rightarrow \text{block-item-list}$

or

$\text{block-item-list opt} \rightarrow \epsilon$

and

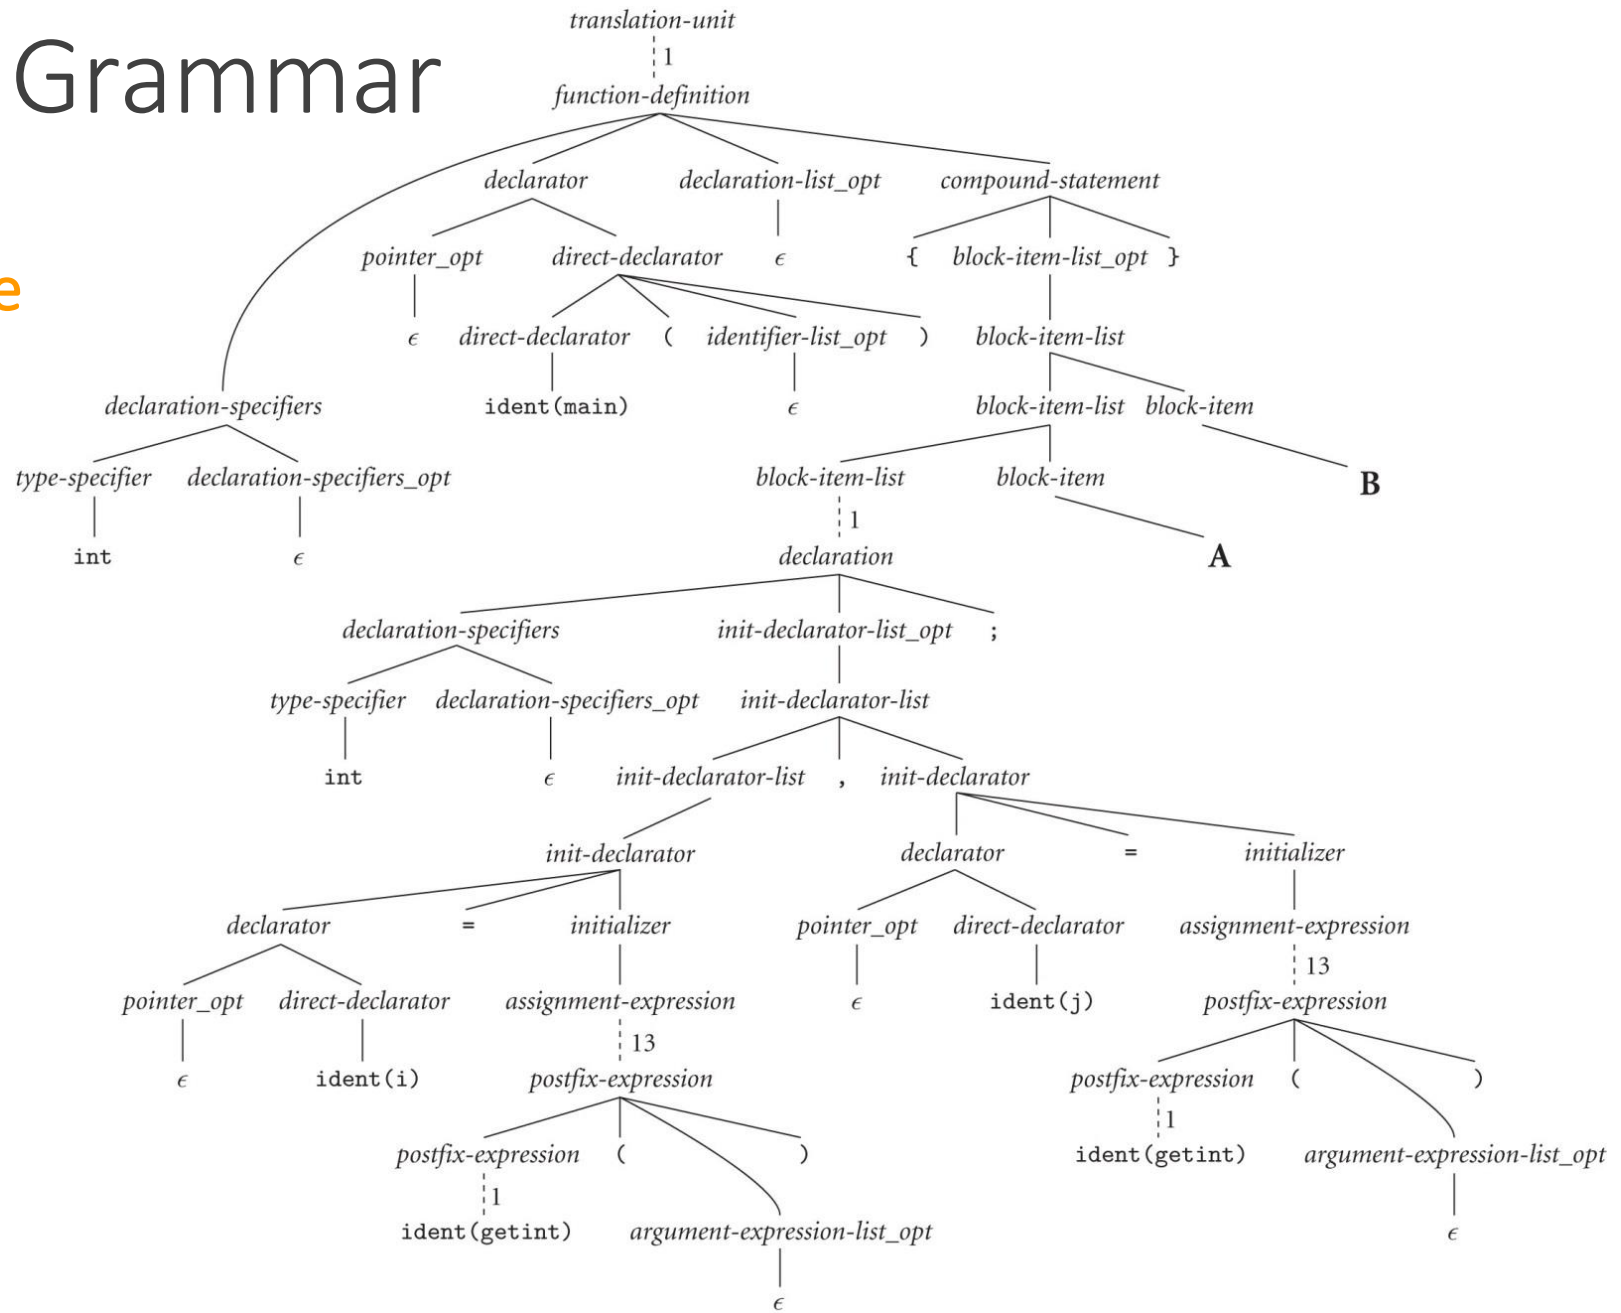

$\text{block-item-list} \rightarrow \text{block-item}$

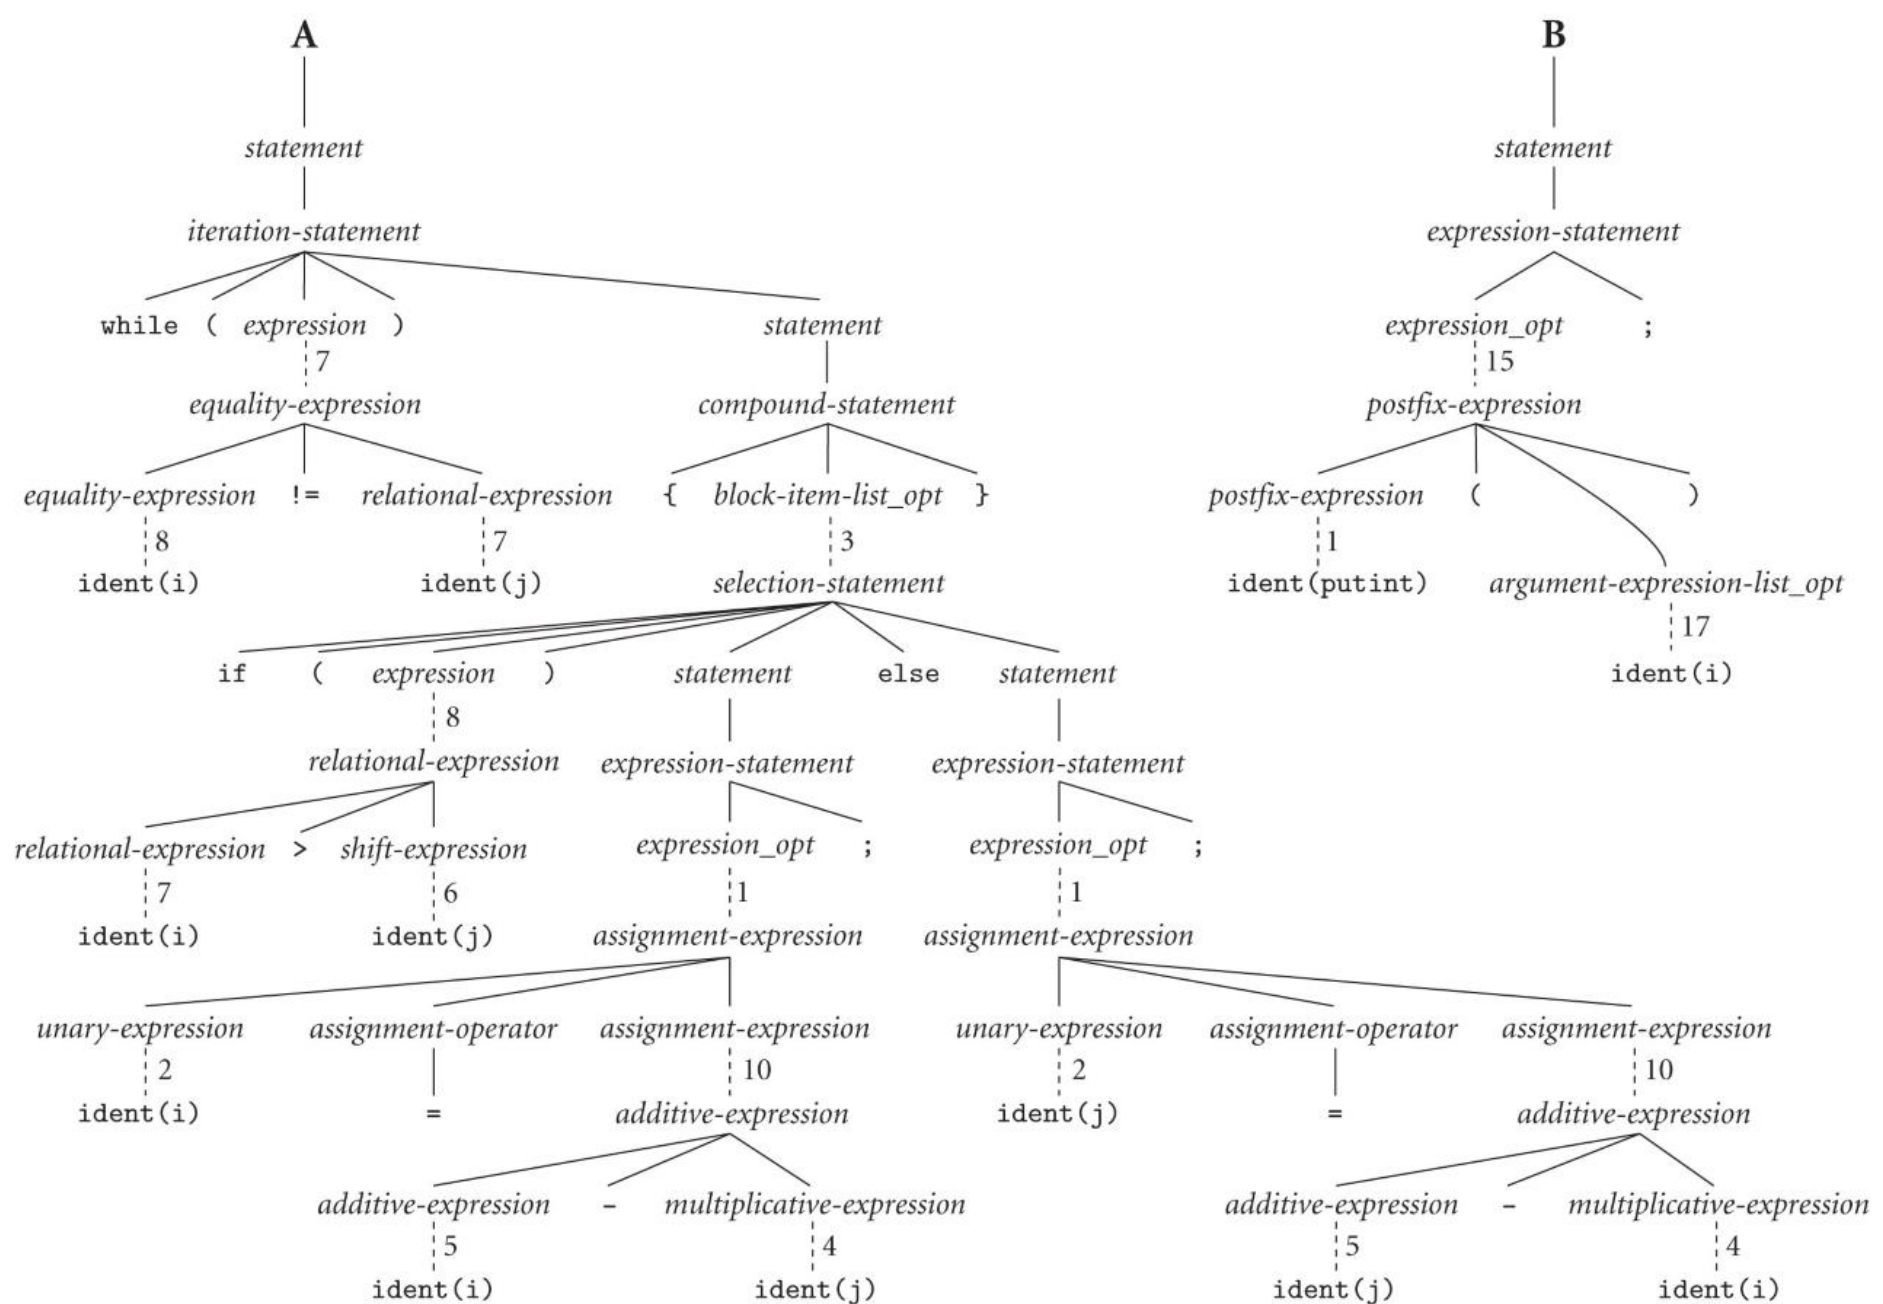

$\text{block-item-list} \rightarrow \text{block-item-list block-item}$

$\text{block-item} \rightarrow \text{declaration}$

$\text{block-item} \rightarrow \text{statement}$

GCD Program Parse Tree
